13. ABSTRACT *(Maximum 200 words)*

The Army's Combat Sample Generator (COSAGE) is a two-sided, symmetrical, high-resolution stochastic simulation model that projects the outcome of ground combat between two forces. Blue force is typically a division; Red force size may be scaled from a fraction of a division to a combined arms army. Because COSAGE is high-resolution (many asset types), it requires extensive data preparation time, and because output is the result of 16-20 replications, substantial simulation run-time.

The analytical model implementation of this thesis is developed to economically project ground combat attrition and munitions expenditures beyond the 48-hour period currently modeled in COSAGE. The implementation evaluates Bayesian estimators of time-period survivorship to estimate expected numbers of kills, both friendly and enemy, during the first 48 hours of combat, then extrapolates those estimates in discrete time steps (here 24 hours) beyond 48 hours. The implementation can be used to project COSAGE output for all combat postures in Northeast and Southwest Asia (NEA and SWA respectively).

An application of the current implementation is to support the warfighting Commanders in Chief (CinC) need to create a Phased Threat Distribution (PTD) in accordance with the Capabilties-Based Munition Requirement Process introduced in June 1997.

EXECUTIVE SUMMARY

The Army's Combat Sample Generator (COSAGE) stochastically simulates the joint action of combat arms in division-level combat. For example, it can represent artillery, Army aviation, and certain engineering and U.S. Air Force functions in direct support of armor and infantry.

COSAGE is a high-resolution simulation that requires extensive preparation time for each of the various combat postures of interest; its run times typically involve 16-20 replications for each posture for a 48-hour period. The results reported are estimated means (averages) of force types and sizes surviving after a given combat period.

This thesis implements and illustrates a simple discrete-time deterministic model that projects or extrapolates initial 48-hour (2 day) COSAGE results to greater time, determined by posture duration. The implementation also provides a diagnostic tool for checking the validity of COSAGE inputs. The implementation employs COSAGE output-based estimators to estimate the total expected number of kills, both friendly and enemy, and the munitions expenditures, by platform type, required to sustain combat.

The implementation can be used to project numbers of surviving platforms for all postures in Northeast and Southwest Asia (NEA and SWA respectively) beyond the 48-hour period currently simulated in COSAGE. Both the single- and multiple-period models significantly reduce the time required to obtain results beyond 48 hours of simulated ground combat; they run quickly on a personal computer. Additionally, the implementation of the analytical model enables analysts to explore numerous "what if" questions concerning parameters, including fire allocation, firing rates and initial platform numbers.

ACKNOWLEDGEMENTS

I would like to thank several people without whom this thesis would not have been possible. First, I would like to thank Mr. Pete Byrne in the Warfighting Analysis Division of J-8. Pete presented me a challenging, relevant problem, and provided unfailing support. Second, I would like to thank Major Jim McMullin at the Center for Army Analysis for his extreme patience trying to educate a Surface Warfare Officer in the fine art of ground combat. Third, I would like to thank Lieutenant Mitchell Kerman for helping me recall much of the Visual Basic programming techniques implemented in this thesis.

I would also like to thank my wife, Elizabeth, and daughter, Lillian, for inspiring me and helping me through the challenge of creating quality work. Without their love and support, this thesis may never have seen the light of day.

Finally, I would like to thank my parents. Everything that I have accomplished I owe to their love and support. This thesis is dedicated in loving memory to my father, Horst M. Schweighofer, the smartest man I will ever know.

I. INTRODUCTION

A. BACKGROUND

Decreasing defense budget funding over the past several years has forced the Department of Defense (DoD) to re-evaluate its spending policies in numerous areas, including that of conventional munitions. As an attempt to curb excessive munitions acquisitions caused by an isolationist "service-centric" approach to munitions requirements generation by the services, the Under Secretary of Defense for Acquisition and Technology introduced Department of Defense Instruction (DODI) 3000.4, Capabilities-Based Munition Requirement (CBMR) Process, in June 1997.

In order to generate battle scenarios for each potential conflict, each service utilizes the Outyear Threat Report (OTR) and Defense Planning Guidance (DPG), two documents dictated by the CBMR Process (Widdowson, 1998). The OTR is produced every odd-numbered year by the Defense Intelligence Agency (DIA), and outlines the DIA's estimate of potential threats for a specified planning horizon (the "outyears") (DODI 3000.4). The DPG, which is published by the Secretary of Defense, outlines national security objectives and policies, military priorities, and projected resource levels available to meet those objectives for the effective DPG period. Included in the DPG are several Illustrative Planning Scenarios (IPSs), which outline hypothetical conflicts, providing a baseline for potential military challenges within the effective years of the DPG. The CBMR Process requires each warfighting CinC, for each given scenario, to produce a Phased Threat Distribution (PTD), identifying friendly forces to which enemy forces (platforms, installations, organizations) are to be assigned for attrition. DODI 3000.4 defines the PTD as

> the CINC's phased assignment of a portion of the enemy's total combat capability (i.e., forces, installations, and organizations) to DOD Component commands. The distribution is a percentage by type of target (e.g., tanks and fighters) by operation plan phases.

The resulting PTD allows each service to estimate the threat it must be prepared to overcome. However, if each service attempts to cover all threats presented for each scenario, munitions over-acquisition is inevitable. It is therefore imperative that targets be equitably apportioned between the available services (Widdowson, 1998).

Once an equitable distribution of enemy targets with minimal overlap of target assignments among the services is created, it is then up to each service to model the ensuing battle. In order to ensure that the applicable Operation Plan (OPLAN) can be successfully completed, each service must generate models to estimate the expected attrition of both friendly and enemy forces, as well as munitions required to meet the assigned goal.

B. THE PROBLEM AND A MODELING APPROACH

Each service historically relies on its own warfighting simulations to determine munitions requirements for each scenario. One of the Army's models, COSAGE (which stands for Combat Sample Generator), is a two-sided, symmetrical, high-resolution stochastic simulation model of combat between two forces, Blue (friendly) and Red (enemy) (U.S. Army Concepts Analysis Agency [CAA], 1993). Running COSAGE requires months of data collection, which is extremely manpower-intensive and expensive, and requires days to run. The purpose of this thesis is to provide Army and joint service analysts with a spreadsheet-based implementation, called DTAM (which stands for Discrete Time Analytical Model), of an analytical model (see Gaver and

Jacobs, 1999) using COSAGE summary output that will quickly and easily estimate expected ground kills and the associated expected Army munitions expenditures for an extended scenario. The spreadsheet is an implementation of an analytical model developed by D.P. Gaver and P.A. Jacobs at the Naval Postgraduate School (Gaver and Jacobs, 1999). Using COSAGE summary data from a 48-hour run as input, the DTAM tool projects future kills for discrete-time (1, 2, or 3-day) time steps, referring to user-defined stopping rules, eliminating the need for additional long, costly COSAGE runs.

C. PROPOSED PROCEDURE

This thesis develops an implementation called DTAM of a deterministic model to predict the munitions required to sustain combat using output from the Army's *Combat Sample Generator* (COSAGE) model; the latter produces results in discrete time (48 hours), so the present model is matched to this data, then extrapolated beyond 48 hours, here in 24-hour (1 day) steps. Parameters of the deterministic model are estimated from summary COSAGE 48-hour output presented in the Killer-Victim (KV) Scoreboards.

The COSAGE summary output KV Scoreboard provides the following information:

1. Combat Posture
2. Shooter
3. Weapon System
4. Munition Fired
5. Target
6. Shots (direct and indirect averaged over 16 or 20 replications)
7. Kills (averaged over 16 or 20 replications)
8. Kills on Dead Targets (averaged over 16 or 20 replications)

The software implements a series of Bayesian estimators to estimate the expected number of kills, both friendly and enemy, and the expected munitions expenditures, by platform type, required to produce these kills from the COSAGE summary output.

In addition to providing a tool for quickly projecting casualties and munitions expenditures, the analytical model allows "what-if" analysis to be conducted on various platform and posture combinations. The proposed process is depicted in Figure 1.1.

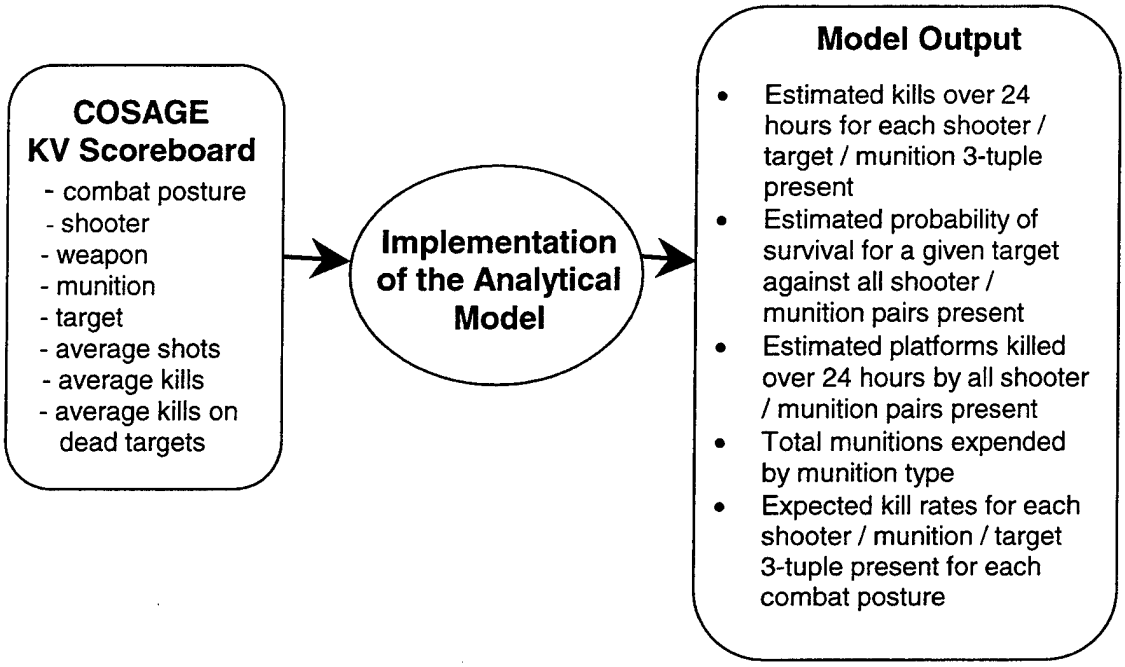

Figure 1.1 The software implements a series of Bayesian estimators to estimate the expected number of kills, and the associated expected munitions expenditures required to produce these kills from COSAGE summary output. The analytical model enables analysts to quickly generate reasonable munitions requirements for each scenario presented.

The analytical model for both single and multiple periods extends the application of COSAGE for all postures in Northeast and Southwest Asia (NEA and SWA respectively) beyond the 48-hour period currently simulated. The analytical model enables analysts to quickly generate reasonable expected munitions requirements for each of the scenarios presented, on a mean basis. *No account is given here of the likely random variability of actual combat, or risk of ammunition shortages.* These issues are saved for future work.

D. MEASURES OF EFFECTIVENESS

Once the analytical model is implemented for the initial 48-hour period using summary COSAGE output, the spreadsheet tool's estimated mean numbers of platforms killed is compared to COSAGE average numbers of kills observed by target type as listed above. A measure of effectiveness used to evaluate the software's plausibility is *the percent error in attrition calculations produced by using the Bayesian estimates.* Once percent error is calculated, an additional, graphical measure of effectiveness is produced by fitting a linear regression of estimated kills produced by the analytical model on actual kills observed in COSAGE summary output, as depicted for the posture NEA "D" (Red Attack vs. Blue Delay) in Figure 1.2. Linear regressions for all combat postures modeled by COSAGE are included as Appendix A. The model fit appears satisfactory for the first 48 hours of combat.

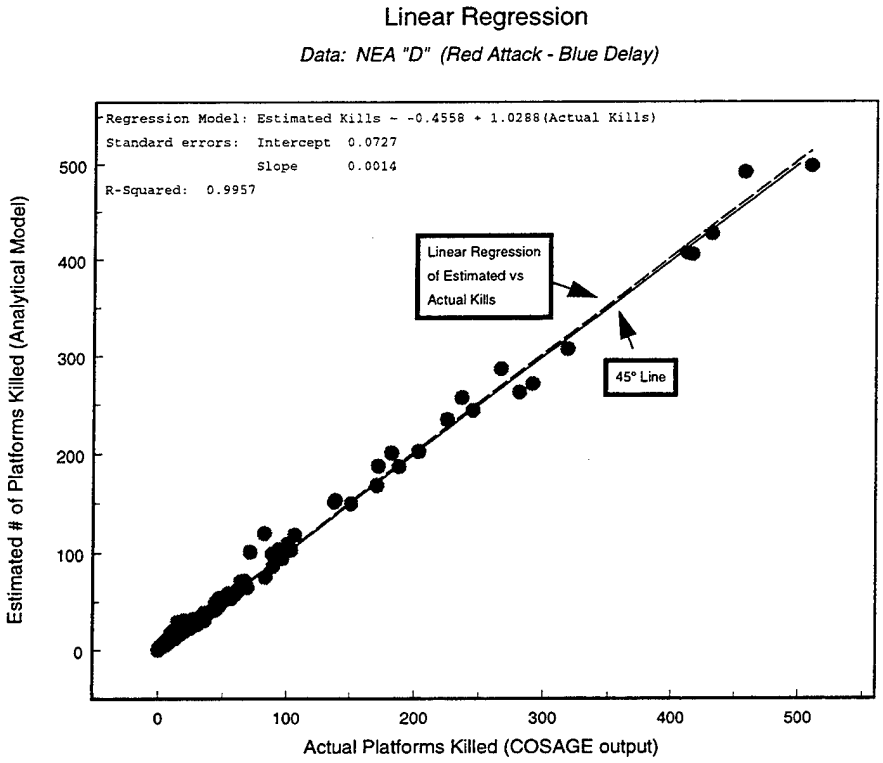

Figure 1.2 A graphical measure of effectiveness is produced by fitting a linear regression of estimated kills produced by the analytical model for 48 hours on actual kills observed in the same 48 hours of COSAGE summary output. Linear regressions for all other combat postures can be found in Appendix B.

E. CONSIDERATIONS

It is important to note that the analytical model is limited in scope. The estimates of expected kills and munitions expenditures presented are based on COSAGE summary output, and therefore do not represent platform interactions for shooter / munition / target 3-tuples not modeled in COSAGE, nor can the model correct any potential simulation deficiencies produced within COSAGE. Additionally, the analytical model is designed to model only Army ground combat of the type presented in COSAGE, and is therefore restricted to the following combat postures presented in COSAGE for either Northeast Asia (NEA) or Southwest Asia (SWA):

1. I - Red Attack / Blue Prepared Defense
2. H - Red Attack / Blue Hasty Defense
3. F - Blue Attack / Red Prepared Defense
4. N - Blue Attack / Red Hasty Defense
5. D - Red Attack / Blue Delay
6. L - Defense Light (Less Intense Static)
7. P - Prep for Attack (Heavy Static)

It is also very important to remember that, while the analytical model produces expected munition expenditures, it does so for (simulated) actual combat only. As with the PTD model, the analytical model does not address "training ammunition, strategic stockpiles, [or] those munitions required to ensure that forward-deployed forces are adequately armed" (Widdowson, 1998).

THIS PAGE INTENTIONALLY LEFT BLANK

II. MODELING APPROACH

A. PROBLEM STATEMENT

Once a PTD is developed and each service is presented its target set in accordance with its role in the applicable OPLAN, the service must predict its munitions requirements based on expected attrition. A tool to approach this problem for the Army is as follows. A Bayesian estimate for the probability with which each target survives a particular munition fired by a particular shooter is obtained from the summary COSAGE output. These estimates are then used to obtain estimates of the expected numbers of targets surviving, expected numbers of targets killed, and expected munitions expended during a 24-hour period. The estimated survival probabilities for each shooter / munition / target 3-tuple for the 24-hour period are then used together with a user-input combat posture to project the numbers of targets surviving for each side through time (24-hour intervals) for a particular scenario.

B. MODELING ASSUMPTIONS

Several assumptions are made in the formulation of the analytical model which is implemented in the software. While the ultimate goal is to capture as much reality in battlefield interactions as possible, some assumptions are required to make the model complete. Additionally, simplifying assumptions provide a manageable model with usable results. Users who rely on the analytical model must be comfortable that the model usefully approximates reality.

The following assumptions are made in the formulation of the analytical model:

1. COSAGE Usefully Models Combat for Particular Postures

Since the deterministic model uses COSAGE summary output, it is assumed that the COSAGE model usefully approximates ground combat. Hence, the deterministic model is subject to all of the assumptions of COSAGE (e.g., ammunition supply is unconstrained).

2. All Forces Operate Along a Single, Continuous Forward Edge of the Battle Area (FEBA)

This simplifying assumption is made to prevent the need to model separate combat postures for different battlefield areas. If combat posture in the multiple-period model is treated as a piston model, similar to that in CEM VI, the entire battlefield is governed by only one combat posture (CAA, 1985). As a result, shooters are provided a uniformly-distributed target set that, although possibly larger than that in discontinuous FEBA models, eludes the difficulties associated with *explicitly* modeling flanks exposed to enemy fire. The current approach *implicitly* models more complicated situations as a simplified force-on-force combat.

3. All Combat Postures Extend No Less Than 24 Hours

Because COSAGE data output is based on a single 48-hour period, and the analytical model on a 24-hour period, it is necessary to assume that the user-prescribed combat posture extends throughout the prescribed modeling period, and, as stated above, across the entire FEBA.

4. All Forces Have COSAGE Battlefield Information

Because the analytical model uses the COSAGE Killer-Victim Scoreboard as its input, the model inherits the battlefield information characteristics generated by COSAGE. Target selection criterion, including target priorities represented by

COSAGE, dictate which shooter / target pairings exist as input to the analytical model (CAA, 1993).

5. Combat for a Blue Division-Sized Force Versus a Red Force Can be Modeled and Used as the Basis for Theater Force Combat

This assumption is made by COSAGE. It is assumed that, by modeling battles at the Blue division level, the model will represent the essence of combat between Blue and Red forces, including key interactions between forces in various combat postures (CAA 1993). Once this assumption is made, it is extended to include the assumption that similar interactions witnessed during combat are scaleable according to force sizes (Blue and Red).

6. Platform Regeneration and Reinforcement Are Not Modeled

In order to simplify the idea of available combat forces, the analytical model does not currently model platform regeneration or reinforcement, although this is feasible (COSAGE models reinforcement, but not regeneration). Thus, the model does not include the logistics pipeline associated with platform repair. Additionally, the model does not explicitly include the effects of such intangibles as crew fatigue and morale (few models do).

7. Individual Shooter Shooting Rate Does Not Change as Combat Progresses

The effective rate at which individual shooters fire their weapons at specific target types is derived from the initial 48 hours of combat generated by COSAGE. This rate is assumed to prevail throughout the remainder of combat. There is no present basis for making any other assumption, but closer examination of combat dynamics could well suggest an improvement.

8. Once a Shooter Designates a Target Set, No Fire Re-Allocation Occurs Based on Target Numbers

Once the estimated individual shooter rate of fire is calculated for each shooter / munition / target 3-tuple in each combat posture, it remains constant. Because estimates of expected kill rate are relatively small for any 24-hour period, the model provides that no target type will be completely attrited to zero, though some approach zero (to a very small order or magnitude); the practical implication is that these *are* zero. In the multiple-period model, although the rate of fire for each individual shooter / munition pair remains constant, the *instantaneous* (actually daily) rate of fire against a given target type is diminished by reductions in the shooter numbers. If the number of a particular target surviving is reduced to zero, the weapons that would fire at it are not reallocated to other targets. Hence, since fire is not re-allocated to different target types; the analytical model does not model fire re-allocation.

9. Each Shooter Has a Non-Increasing Target Supply

The assumption of a diminishing target base allows for the notion of an expected kill rate for each shooter / target pair based on current availability. While not all shooter / target pairs may be available at all times, it is assumed that each shooter will attack those targets present, and that COSAGE usefully models the target acquisition process.

10. Ammunition Supply is Unlimited

As in COSAGE, ammunition supplies are assumed to be unlimited, and battlefield equipment such as tanks begin each battle with a full, inexhaustible onboard munitions load. By making this assumption, the model avoids the possibility of posture transitions based on factors (possibly realistic) other than available combat forces. Additionally, this

assumption retains the concept of an effective kill rate for each target / munition / target 3-tuple present.

11. Some Indirect Fire Weapons are Treated as Direct Fire Weapons

Based on an interview with Professor Sam Parry at the Naval Postgraduate School (Parry, 1999), various indirect fire weapons and their munitions may be treated as direct fire systems. Based on this information, the analytical model implementation treats Multiple-Launch Rocket Systems (MLRS), listed as platform "UMLRS," and Precision-Guided Munitions (PGM), listed as munition "PGM," as direct fire weapons. It is possible that, when summed, average shots attributed to a particular target may exceed the average total shots recorded for the given munition. As a result of this assumption, in the event that COSAGE reported kills exceed shots fired, the implementation sets kills equal to the number of shots fired. This assumption is temporary and convenient, though not easily defensible, and should be resolved in future work.

12. Mines are Treated as One Platform Firing Indirect Fire Munitions

COSAGE reports minefields and fired mines as kill-producing platforms with an initial number set to zero. Since minefields and fired mines produce positive kills, the analytical model treats them as one platform firing indirect fire munitions in order to calculate plausible kills attributable to mines. The analytical model does not currently model mine-clearing operations, except as reflected in the COSAGE output.

C. DATA SOURCES

COSAGE summary reports, provided by the Center for Army Analysis (CAA), provide all the data used in the analytical model. No data require dedicated collection

efforts; the data are also used by various existing higher-resolution theater level simulation models, including CEM VI (Appleget, 1995).

COSAGE is a division level stochastic simulation designed to provide planners data to calculate ammunition expenditures and equipment losses, and to provide equipment losses and munitions expenditures for use in simulation postprocessors (Appleget, 704). COSAGE is used primarily as a method to calibrate data for theater level models, such as CEM VI. COSAGE input includes organizational structures, personnel and equipment strengths, weapon types, numbers of forces and their characteristics, and types, quantities and technical characteristics of munitions for all forces (CAA, 1993). As listed in Chapter I, COSAGE output utilized in the analytical model consists of the killer / victim scoreboards, which provide data on posture, shooter / munition / target 3-tuples present, average shots, average kills and average kills on dead targets.

III. THE SINGLE-PERIOD MODEL

A. DISCUSSION

The single-period model, created by Gaver and Jacobs (1999), is a discrete-time formulation based on a series of Bayesian survival probability estimates for both direct and indirect fire cases (see Section 3). As stated earlier, Bayesian estimates for the probability a target survives munitions fired by a particular shooter are obtained from the summary COSAGE output. These estimates are then used to obtain the following:

1. Estimated kills over 24 hours for each shooter / munition / target 3-tuple present in the given scenario.
2. Estimated probability of survival for a given target against all shooter / munition pairs present.
3. Estimated platforms killed over 24 hours by all shooter / munition pairs present.
4. Estimated total munitions expended by munition type.
5. Expected kill rates for each shooter / munition / target 3-tuple present for each combat posture.

The single-period model is implemented in Visual Basic, and is executed via macros from within the associated Microsoft Excel workbook. A separate Excel workbook, containing all computations for either NEA or SWA, is created for each prescribed combat posture. Because each combat posture formulation relates so closely to its COSAGE summary data source, typical scenario runs generate an Excel workbook containing approximately 170,000 entries. A Pentium II running at 400 megahertz with 96 megabytes of RAM requires approximately 20 minutes to perform all calculations required to produce the estimates listed above for each combat posture scenario.

B. VARIABLE CONVENTIONS

In order to aid understanding of the single-period model outlined below, as well as the full single-period model formulation (Gaver and Jacobs, 1999), all state variables will be referenced in accordance with the following conventions:

1. Although each COSAGE data set is the result of either 16 or 20 replications, all references to COSAGE output assume an average value over all replications.

2. COSAGE summary output is produced for a 48-hour period. Unless otherwise indicated, all values and estimates generated by the single-period analytical model represent a 48-hour period.

3. The time index listed in single-period state variables as 0 indicates the 48-hour period modeled by the single-period implementation. In the multiple-period implementation, the time index 0 will be replaced by t, which indicates the various force element counts at the number of days predicted (e.g., 1, 2, etc.).

4. All indices indicating actual forces consist of a single uppercase character (e.g., B indicates Blue forces, R indicates Red forces).

5. All indices with compound subscripts will list subscripts according to the following convention:
   a The first subscript indicates the *firing* force.
   b The second subscript indicates the *receiving* force.
   (e.g., N_{BR} indicates shots by Blue forces against Red forces)

C. STATE VARIABLES

$B(j_B,t)$	Number of Blue platforms of type j_B at time t
$R(j_R,t)$	Number of Red platforms of type j_R at time t

D. COSAGE DATA FOR THE 48-HOUR CAMPAIGN

Reps	Number of Replications indicates the number of COSAGE replications run for the current posture

$\overline{n}_{BR}(j_B, w_B, j_R, 0)$ Shots (Blue on Red – direct fire)

indicates average number of shots taken over all replications by one Blue shooter of type j_B firing weapon w_B against all Red targets of type j_R as indicated by COSAGE for the initial 48-hour period

$\overline{n}_{RB}(j_R, w_R, j_B, 0)$ Shots (Red on Blue – direct fire)

indicates average number of shots taken over all replications by one Red shooter of type j_R firing weapon w_R against all Blue targets of type j_B as indicated by COSAGE for the initial 48-hour period

$\overline{N}_{BR}(j_B, w_B, j_R, 0)$ Shots (Blue on Red – direct fire)

indicates average number of shots taken over all replications by all Blue shooters of type j_B firing weapon w_B against all Red targets of type j_R as indicated by COSAGE for the initial 48-hour period

$\left\{\overline{N}_{BR}(j_B, w_B, j_R, 0) = B(j_B, 0) \cdot \overline{n}_{BR}(j_B, w_B, j_R, 0)\right\}$

$\overline{N}_{RB}(j_R, w_R, j_B, 0)$ Shots (Red on Blue – direct fire)

indicates average number of shots taken over all replications by all Red shooters of type j_R firing weapon w_R against all Blue targets of type j_B as indicated by COSAGE for the initial 48-hour period

$\left\{\overline{N}_{RB}(j_R, w_R, j_B, 0) = R(j_R, 0) \cdot \overline{n}_{RB}(j_R, w_R, j_B, 0)\right\}$

$N_{BR}(j_B, w_B, j_R, 0)$ Shots (Blue on Red – direct fire)

indicates total number of shots taken over all replications by all Blue shooters of type j_B firing weapon w_B against all Red targets of type j_R for the initial 48-hour COSAGE period

$\left\{N_{BR}(j_B, w_B, j_R, 0) = \overline{N}_{BR}(j_B, w_B, j_R, 0) \cdot Reps\right\}$

$N_{RB}(j_R, w_R, j_B, 0)$ Shots (Red on Blue – direct fire)

indicates total number of shots taken over all replications by all Red shooters of type j_R firing weapon w_R against all Red targets of type j_B for the initial 48-hour COSAGE period

$\left\{N_{RB}(j_R, w_R, j_B, 0) = \overline{N}_{RB}(j_R, w_R, j_B, 0) \cdot Reps\right\}$

$\overline{S}_{BR}(j_B, w_B, 0)$ Shots (Blue on Red – indirect fire)

indicates average number of indirect shots taken over all replications by all Blue shooters of type j_B firing weapon w_B against all Red targets as indicated by COSAGE for the initial 48-hour period

$\overline{S}_{RB}(j_R, w_R, 0)$ Shots (Red on Blue – indirect fire)

indicates average number of indirect shots taken over all replications by all Red shooters of type j_R firing weapon w_R against all Blue targets as indicated by COSAGE for the initial 48-hour period

$S_{BR}(j_B, w_B, 0)$ Shots (Blue on Red – indirect fire)

indicates total number of indirect shots taken over all replications by all Red shooters of type j_R firing weapon w_R against all Blue targets for the initial 48-hour COSAGE period

$\{S_{BR}(j_B, w_B, 0) = \overline{S}_{BR}(j_B, w_B, 0) \cdot Reps\}$

$S_{RB}(j_R, w_R, 0)$ Shots (Red on Blue – indirect fire)

indicates total number of indirect shots taken over all replications by all Red shooters of type j_R firing weapon w_R against all Blue targets for the initial 48-hour COSAGE period

$\{S_{RB}(j_R, w_R, 0) = \overline{S}_{RB}(j_R, w_R, 0) \cdot Reps\}$

$\overline{K}_{BR}(j_B, w_B, j_R, 0)$ Kills (Blue on Red)

indicates average number of Red targets of type j_R killed over all replications by Blue shooters of type j_B firing weapon w_B for the initial 48-hour COSAGE period

$\overline{K}_{RB}(j_R, w_R, j_B, 0)$ Kills (Red on Blue)

indicates average number of Blue targets of type j_B killed over all replications by Red shooters of type j_R firing weapon w_R for the initial 48-hour COSAGE period

$K_{BR}(j_B, w_B, j_R, 0)$ Kills (Blue on Red)

indicates total number of Red targets of type j_R killed over all replications by Blue shooters of type j_B firing weapon w_B for the initial 48-hour COSAGE period

$\{K_{BR}(j_B, w_B, j_R, 0) = \overline{K}_{BR}(j_B, w_B, j_R, 0) \cdot Reps\}$

$K_{RB}(j_R, w_R, j_B, 0)$ Kills (Red on Blue)

indicates total number of Blue targets of type j_B killed over all replications by Red shooters of type j_R firing weapon w_R for the initial 48-hour COSAGE period

$\{K_{RB}(j_R, w_R, j_B, 0) = \bar{K}_{RB}(j_R, w_R, j_B, 0) \cdot Reps\}$

E. SINGLE-PERIOD MODEL EXPLANATION

The following introduces the single-period model user to the format of the model as it is implemented in Microsoft Excel™ 97. The complete Visual Basic code for the single-period model implementation is included as Appendix B.

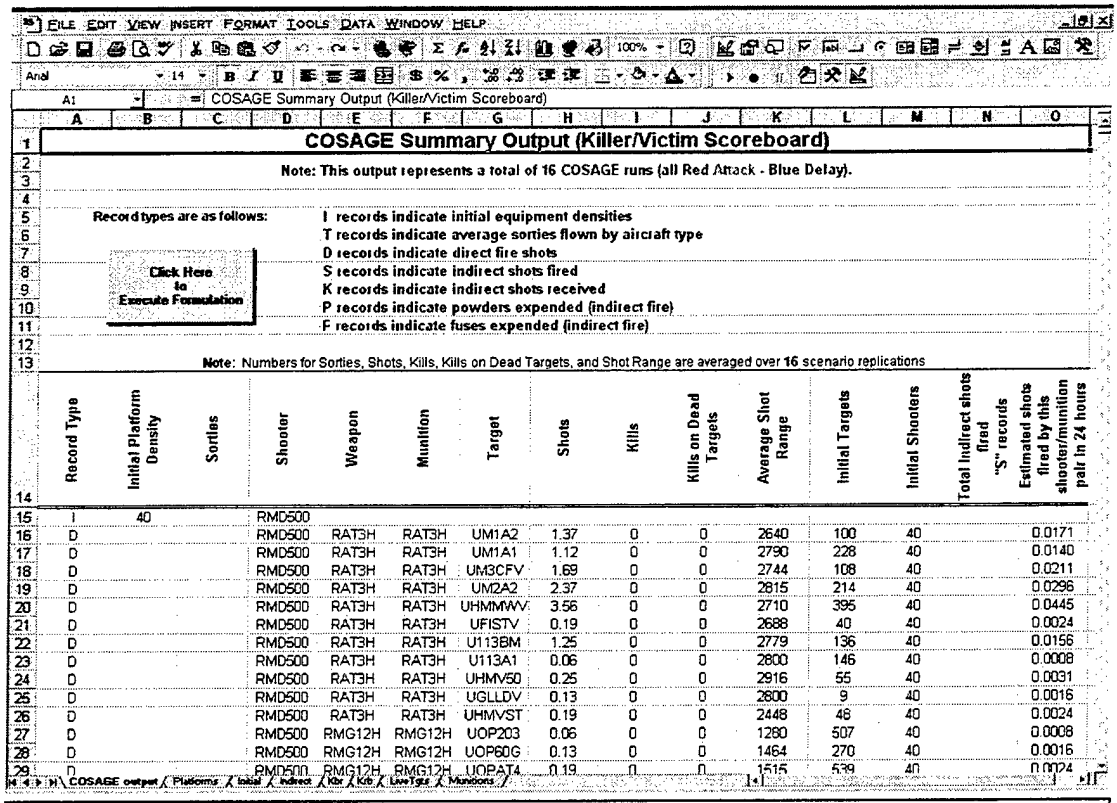
1. Excel Workbook Format

The single-period model for each of the seven combat postures, for both NEA and SWA, is implemented in a separate Excel workbook. For illustrative purposes, all Excel worksheets included in this section represent the NEA "D" (Red Attack vs. Blue Delay) combat posture. Each workbook consists of the following eight worksheets, which are explained in the next section:

a. COSAGE output
b. Platforms
c. Initial
d. Indirect
e. Kbr
f. Krb
g. LiveTgts
h. Munitions

In the first worksheet of the Excel workbook, "COSAGE output," the user will find information concerning data from the COSAGE summary output, including the combat posture modeled by the active workbook (see Figure 3.1). As depicted in Figure 3.1, the second line of the worksheet COSAGE output indicates the combat posture modeled, as well as information concerning the number of COSAGE replications run to

produce the output shown. Additionally, included on the first worksheet of each workbook, COSAGE output, is a command button labeled "Click Here to Execute Formulation" which, when clicked, will execute the Visual Basic code required to carry out all calculations for estimated survival and kill probabilities and munitions expenditures outlined in Section 3, and to populate the entire workbook. Since all calculations are executed when the "Execute" button is clicked, the user needs only to click it once for each new combat posture. By using the command button, the user is freed from the task of running each Visual Basic macro individually, and the potential error of executing a macro before prior worksheets have been populated with data required therein.



COSAGE Summary Output (Killer/Victim Scoreboard)

Note: This output represents a total of 16 COSAGE runs (all Red Attack - Blue Delay).

Record types are as follows:

I records indicate initial equipment densities
T records indicate average sorties flown by aircraft type
D records indicate direct fire shots
S records indicate indirect shots fired
K records indicate indirect shots received
P records indicate powders expended (indirect fire)
F records indicate fuses expended (indirect fire)

Click Here to Execute Formulation

Note: Numbers for Sorties, Shots, Kills, Kills on Dead Targets, and Shot Range are averaged over 16 scenario replications

Record Type	Initial Platform Density	Sorties	Shooter	Weapon	Munition	Target	Shots	Kills	Kills on Dead Targets	Average Shot Range	Initial Targets	Initial Shooters	Total Indirect shots fired "S" records	Estimated shots fired by this shooter/munition pair in 24 hours

Figure 3.1 Each Excel workbook consists of eight worksheets, which are accessed by clicking on the tabs labeled "COSAGE etc," etc. along the bottom of the Excel screen.

2. Excel Worksheets

This section is designed to familiarize the user with each of the eight worksheets included in the Excel workbook, including a brief explanation of the key fields used in the analytical model.

a. COSAGE Output

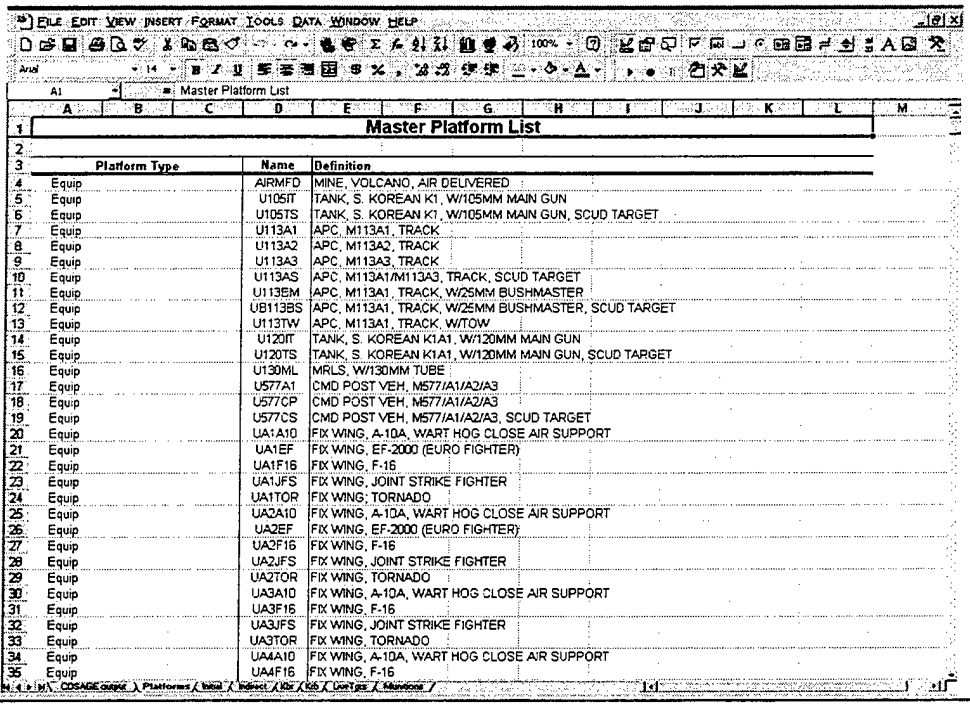
This worksheet displays the COSAGE summary data used in the analytical model, and is the Excel equivalent to the Unix-based summary output produced by CAA for use in theater models, with the following additions (see Figure 3.1). Columns L through N, which include data concerning initial platform numbers and totals for indirect shots fired, as well as column O, which estimates total shots fired over 24 hours by each shooter / munition pair present, are populated once the formulation is executed. The estimate of total shots fired over 24 hours by each shooter / munition pair (column O) is then used by the analytical model in successive time periods.

b. Platforms

The "Platforms" worksheet provides the user with a list of all platforms, weapon systems and munition types used in COSAGE (see Figure 3.2). The section "Name" lists abbreviations used by COSAGE to describe each platform type outlined above, and is followed by the platform description in "Definition." Of special note is the convention used by COSAGE to delineate between Blue and Red platform types. All force-specific platform names, following COSAGE naming standards, begin with either an "R," indicating Red forces, or "U," indicating Blue (or allied) forces.

c. Initial

The worksheet labeled "Initial" provides the analytical model a list of all platforms modeled in the prescribed COSAGE combat posture, as well as the initial number of each platform present in the "Initial Platform Density" section (see Figure 3.3).



Master Platform List

Platform Type	Name	Definition
Equip	AIRMFD	MINE, VOLCANO, AIR DELIVERED
Equip	U105IT	TANK, S. KOREAN K1, W/105MM MAIN GUN
Equip	U105TS	TANK, S. KOREAN K1, W/105MM MAIN GUN, SCUD TARGET
Equip	U113A1	APC, M113A1, TRACK
Equip	U113A2	APC, M113A2, TRACK
Equip	U113A3	APC, M113A3, TRACK
Equip	U113AS	APC, M113A1/M113A3, TRACK, SCUD TARGET

UM120Z	54
UH155A	80

Figure 3.3 The "Initial" worksheet provides Red and Blue initial platform numbers for the designated COSAGE combat posture.

d. Indirect

The "Indirect" worksheet provides the analytical model with a list of indirect fire shots, averaged over total COSAGE replications, for each shooter / weapon / munition 3-tuple present (see Figure 3.4).

e. Kbr and Krb

The "Kbr" and "Krb" worksheets provide both the user and the analytical model with Bayesian estimates for survival probabilities, as well as the estimated average kill rate for each shooter / munition / target 3-tuple present (see Figure 3.5). The worksheets also provide the model firing rates (see Section 3, equations 3.4 and 3.10) for each shooter / munition / target 3-tuple present for a 24-hour period (column I), which is required to project the model beyond the initial 48 hours modeled by COSAGE. The

worksheet "Kbr" shown in Figure 3.5 represents Blue forces killing Red forces. All information shown is identical for worksheet "Krb," with the exception that "Krb" models Red forces killing Blue forces.

Figure 3.5 The worksheets "Kbr" and "Krb" represent survival estimates and estimated kill rates for Blue forces killing Red and Red forces killing Blue respectively.

f. LiveTgts

Worksheet "LiveTgts" pulls Bayesian estimates, described in Section 3, for survival probability from worksheets "Kbr" and "Krb," using them to calculate estimated number of targets killed for each shooter / munition / target 3-tuple present, as well as estimated cumulative number of kills for each target type present for both 48 and 24-hour periods (see Figure 3.6). Since estimating cumulative platform kills in column O is an additive process, it is important that, in order to estimate total cumulative kills, the user read the last entry before the break for each target type. For an explanation of "Calculated Error" (column R), see Equation (3.14).

Figure 3.7 Worksheet "Munitions" provides estimated total munitions expenditures for each shooter / munition / target 3-tuple present, as well as estimated cumulative munitions expenditures by munition type.

3. Preliminary Calculations

This section introduces the reader to some of the key calculations implemented by the analytical model. An input into the analytical model, the Bayesian estimates for survival probability, were introduced by Professor Gaver and Professor Jacobs in their paper *Discrete-Time Analytical Models for Use in Combat Systems Studies that Augment Simulation Models ("COSAGE")* (Gaver and Jacobs, 1999) in order to avoid over-emphasis on literally zero platform kills by COSAGE (a result of random sampling). Here the prior probability distribution has been *assumed to be uniform(0, 1).* Improvements can be made using actual individual shooter / weapon / target data. This is left for future work.

Estimators

Direct Fire

The Bayesian estimates for direct fire survival and kill probabilities are obtained for each combat posture, and are formulated on the assumption that each direct fire shot fired by a particular shooter is aimed at only one target. The direct fire assumption in DTAM is that, for every shooter / munition / target 3-tuple, there is a miss probability q such that q^x is the probability of surviving x shots. In other words, shots are assumed to be independent. The parameter q must be estimated from COSAGE output, but there is a danger that the estimate may be near the extreme values of 0 or 1 because of small statistical samples. We therefore adopt a Bayesian point of view where q is initially supposed to uniformly random in the interval [0, 1]. The estimate $\hat{q}$ is then taken to be the mean of the posterior distribution (Gaver and Jacobs, 1999). This point of view is responsible for the terms $1/Reps$ and $2/Reps$ in the estimates specified below; the effect is to move estimates away from extreme values toward the mean of the distribution (½). Results of these estimates can be seen in worksheets "Kbr," "Krb," and "LiveTgts."

The Bayesian estimate for the single shot survival probability for a Red target of type j_R being fired on by a Blue shooter of type j_B firing munition w_B for the initial COSAGE 48-hour period is

$$\hat{q}(j_B, w_B, j_R) = \frac{\bar{N}_{BR}(j_B, w_B, j_R, 0) - \bar{K}_{BR}(j_B, w_B, j_R, 0) + (1/Reps)}{\bar{N}_{BR}(j_B, w_B, j_R, 0) + (2/Reps)} \quad (3.1)$$

The estimate for the initial 24-hour survival probability of one Red target of type j_R against *all* shots by a given Blue shooter / munition pair (j_B, w_B) is

$$\hat{q}_{24}(j_B, w_B, j_R) = \left(\hat{q}(j_B, w_B, j_R)\right)^{(1/2)\left(\bar{N}_{BR}(j_B, w_B, j_R, 0) / \bar{R}(j_R, 0)\right)} \quad (3.2)$$

where the exponent ½ scales results from 48 to 24 hours

The estimate for the average number of shots per Blue shooter of type j_B firing direct fire munition w_B at Red targets of type j_R over any 24-hour period is

$$\rho_{BR}(j_B, w_B, j_R) = \frac{1}{2}\left(\frac{\bar{N}_{BR}(j_B, w_B, j_R, 0)}{B(j_B, 0)}\right) \tag{3.3}$$

The estimate for the average rate of kill of Red targets of type j_R by each Blue shooter of type j_B firing munition w_B at Red target of type j_R over any 24-hour period is estimated as

$$\delta(j_B, w_B, j_R) = \rho_{BR}(j_B, w_B, j_R)\left(1 - \hat{q}(j_B, w_B, j_R)\right) \tag{3.4}$$

The estimate for the expected number of kills of Red targets of type j_R by all Blue shooters of type j_B firing munition w_B in a 24-hour period starting at time t is

$$R(j_R, t) - R(j_R, t+1) = \left\{1 - \hat{q}(j_B, w_B, j_R)^{\left(\frac{\rho_{BR}(j_B, w_B, j_R)\cdot B(j_B, t)}{R(j_R, t)}\right)}\right\}\{R(j_R, t)\} \tag{3.5}$$

Indirect (or Area) Fire

Unlike direct fire, indirect fire does not make the assumption that each shot fired by a given shooter / munition pair is directed at a single target. One indirect fire shot can kill more than one target if multiple targets are within its lethal area footprint. The COSAGE Killer-Victim scoreboard introduces the notion of "K" shots, which indicate the indirect fire shots "perceived" by intended targets. The implementation of the analytical model does not address "K" shots ("K" records in COSAGE output), utilizing "S" records instead to account for actual indirect fire shots fired by Blue and Red forces.

A Bayesian estimate for the survival probability for one Red platform of type j_R against a single shot by a shooter of type j_B firing munition w_B, using the initial 48-hour COSAGE output, is

$$\hat{q}(j_B, w_B, j_R) = 1 - \frac{\overline{K}_{BR}(j_B, w_B, j_R, 0) + (1/Reps)}{\overline{S}_{BR}(j_B, w_B, 0) \cdot R(j_R, 0) + (2/Reps)} \tag{3.6}$$

A Bayesian estimate for the initial 24-hour survival probability for a Red platform j_R against $(\frac{1}{2})\,\overline{S}_{BR}(j_B, w_B, 0)$ shots is

$$\hat{q}_{24}(j_B, w_B, j_R) = \left[\hat{q}(j_B, w_B, j_R)\right]^{(1/2)\overline{S}_{BR}(j_B, w_B, 0)} \tag{3.7}$$

where the exponent ½ scales results from 48 to 24 hours

The estimated rate at which each Blue shooter of type j_B fires indirect fire munitions of type w_B at Red targets of type j_R over any 24-hour period is

$$\rho_{BR}(j_B, w_B, j_R) = \frac{1}{2}\left(\frac{\overline{S}_{BR}(j_B, w_B, 0)}{B(j_B, 0)}\right) \tag{3.8}$$

The estimate for the average rate of kill of Red targets of type j_R by each Blue shooter of type j_B firing indirect fire munition w_B over any 24-hour period is

$$\delta(j_B, w_B, j_R) = \rho(j_B, w_B, j_R)\left(1 - \hat{q}(j_B, w_B, j_R)\right) \tag{3.9}$$

The Bayesian estimate for the expected number of indirect kills of Red targets of type j_R by all Blue shooters of type j_B in 24 hours starting at time t is

$$R(j_R, t) - R(j_R, t+1) = \left\{1 - \hat{q}(j_B, w_B, j_R)^{\rho_{BR}(j_B, w_B, j_R) \cdot B(j_B, t)}\right\}\left\{R(j_R, t)\right\} \tag{3.10}$$

Estimated Cumulative Probability of Survival

The estimator for the cumulative expected survival probability against direct *or* indirect fire for target j_R against all shots from all shooter / weapon pairs present firing at that target for any 24-hour period starting at time t is

Direct Fire

$$\prod_{j_B}\prod_{w_B}\left(\hat{q}(j_B,w_B,j_R)\right)^{\rho_{BR}(j_B,w_B,j_R)\cdot B(j_B,t)/R(j_R,t)},\ \forall j_R,t \tag{3.11}$$

Indirect Fire

$$\prod_{j_B}\prod_{w_B}\left(\hat{q}(j_B,w_B,j_R)\right)^{\rho_{BR}(j_B,w_B,j_R)\cdot B(j_B,t)},\ \forall j_R,t \tag{3.12}$$

It is important to note that the estimators described above are shown for illustrative purposes only. Since targets must survive shots from both direct and indirect fire, the implementation of the analytical model uses the product of Equations 3.11 and 3.12 to describe the cumulative survival probability against both direct and indirect fire.

The estimator for the cumulative expected survival probability for Red target j_R against all shots from all Blue shooter / munition pairs (j_B,w_B) present for any 24-hour period starting at time t is

$$\hat{q}_{surv}(j_B,j_R,t)=\text{Formula}(3.11)\cdot\text{Formula}(3.12),\forall j_R,t \tag{3.13}$$

Computing Percent Error for Estimated Kills

When implementing the Bayesian estimates, one measure of effectiveness used to evaluate the software's plausibility is the percent error in attrition calculations produced by using the Bayesian estimates when compared to the initial COSAGE 48-hour period.

The estimate for the error in attrition of Red targets of type j_R being attrited by Blue targets of type j_B firing munition w_B is

$$e = \frac{\left| R(j_R,0)\left(1-\hat{q}_{surv}(j_B,w_B,j_R,0)^2\right) - \bar{K}_{BR}(j_B,w_B,j_R,0) \right|}{R(j_R,0)} \tag{3.14}$$

where the exponent 2 scales results for $\hat{q}_{surv}(j_B,w_B,j_R,0)$ from 24 to 48 hours. There is, of course, a corresponding formula for Blue attrition.

IV. THE MULTIPLE-PERIOD MODEL

A. DISCUSSION

Like the single-period analytical model, the multiple-period model is a discrete-time formulation based on Bayesian estimators of survival probabilities formulated by Professors Gaver and Jacobs. The multiple-period model utilizes the same Bayesian survival probability estimates implemented in the single-period model for both direct and indirect fire cases. All state variables introduced in the single-period model carry over to the multiple period model, with the addition of an active time subscript *t*. Unlike the single-period model, in which the subscript *t* set to zero indicates the initial 48-hour timeframe, the multiple-period model uses *t* as a 24-hour period (this can be altered at will, e.g., to 12-hour periods). The Bayesian 24-hour survival estimates and shooting rates calculated in the single period model for use in the multiple-period model are utilized to produce the following:

1. Estimated platforms surviving after the user-defined 24-hour period for each shooter / munition / target 3-tuple present for the user-specified combat posture.

2. Estimated munitions expenditures for the user-defined 24-hour period for each shooter / munition / target 3-tuple present for the user-specified combat posture.

3. Expected total munitions expended by munition type for the user-defined 24-hour period and combat posture.

The Visual Basic macros implemented in the multiple-period model require approximately six minutes to produce the output described above for each theater / posture combination for each 24-hour period. A sample of the Visual Basic formulation for the multiple-period model is included as Appendix C.

B. MULTIPLE-PERIOD MODEL EXPLANATION

As stated above, the complete implementation of the multiple-period model formulation, created by Professors Gaver and Jacobs is included as Appendix C. The following introduces the multiple-period model user to the format of the model as it is implemented in Excel workbooks.

1. Excel Workbook Format

The multiple-period model for each of the seven combat postures, for both NEA and SWA, is implemented in an expanded version of the Excel workbook utilized in the single-period model. Each workbook in the multiple-period model adds the following six worksheets to those for the single-period model described in Chapter III. The six worksheets, which are explained in the next section, are:

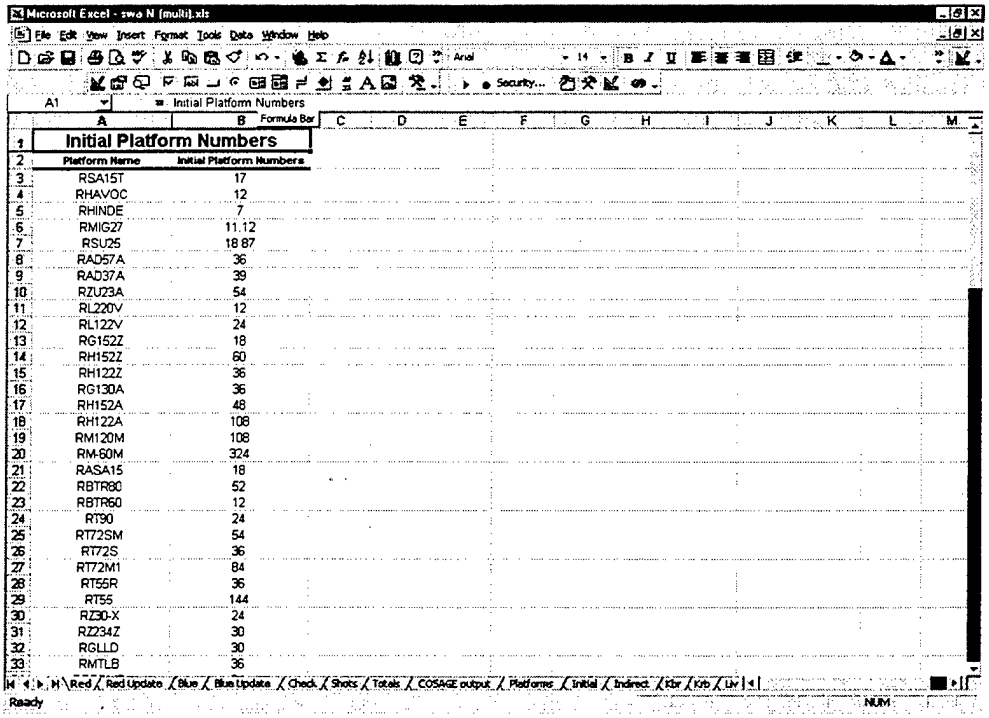
1. Red
2. Blue
3. Red Update
4. Blue Update
5. Shots
6. Totals

2. Excel Worksheets

This section is designed to familiarize the multiple-period model user with each of the six worksheets added to the Excel workbook for each combat posture, including a brief description of the key fields used in the analytical model. For illustrative purposes, all worksheets shown in this section are from combat posture SWA "N" (Blue Attack vs. Red Hasty Defense).

a. Red and Blue

The first two workbooks, "Red" and "Blue" provide the analytical model implementation the initial numbers of each platform present at time $t = 0$ (see Figure 4.1). Both "Red" and "Blue" worksheets are populated by running the Excel CosageUpdate macro, in which all initial numbers are drawn from the COSAGE Killer-Victim Scoreboard and apportioned between Red and Blue platforms to reduce looping times when the model is implemented.



Initial Platform Numbers	
Platform Name	Initial Platform Numbers
RSA15T	17
RHAVOC	12
RHINDE	7
RMIG27	11.12
RSU25	18.87

RZ234Z	30
RGLLD	30
RMTLB	36

Figure 4.1 The "Red" and "Blue" worksheets provide the multiple-period model with initial numbers of each platform at time $t = 0$.

b. Red Update

This worksheet, in conjunction with the worksheet "Blue Update," provides the user a simple model interface by which to control the number of 24-hour

periods to be modeled. Beginning with the information concerning platforms and their initial numbers provided in worksheet "Red," the "Red Update" worksheet calculates estimates of surviving Red platforms for successive 24-hour periods as a function of remaining Blue platforms, shots and kills using the Bayesian survival estimates introduced in Chapter III, Section E. In addition, the "Red Update" worksheet provides a worksheet-based interface which allows the user to simply designate how many 24-hour periods to model, for both Red and Blue forces, by entering an integer value in the dialog box and clicking the command bar (see Figure 4.2).

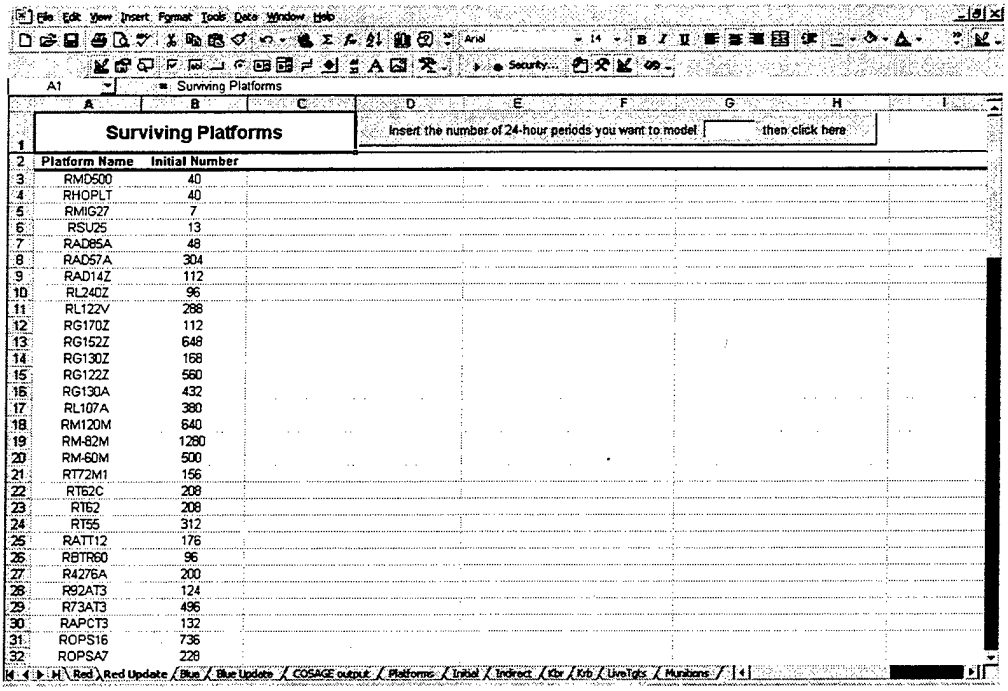

Figure 4.2 The "Red Update" worksheet includes a command bar, which allows the user to dictate how many consecutive 24-hour combat periods to model.

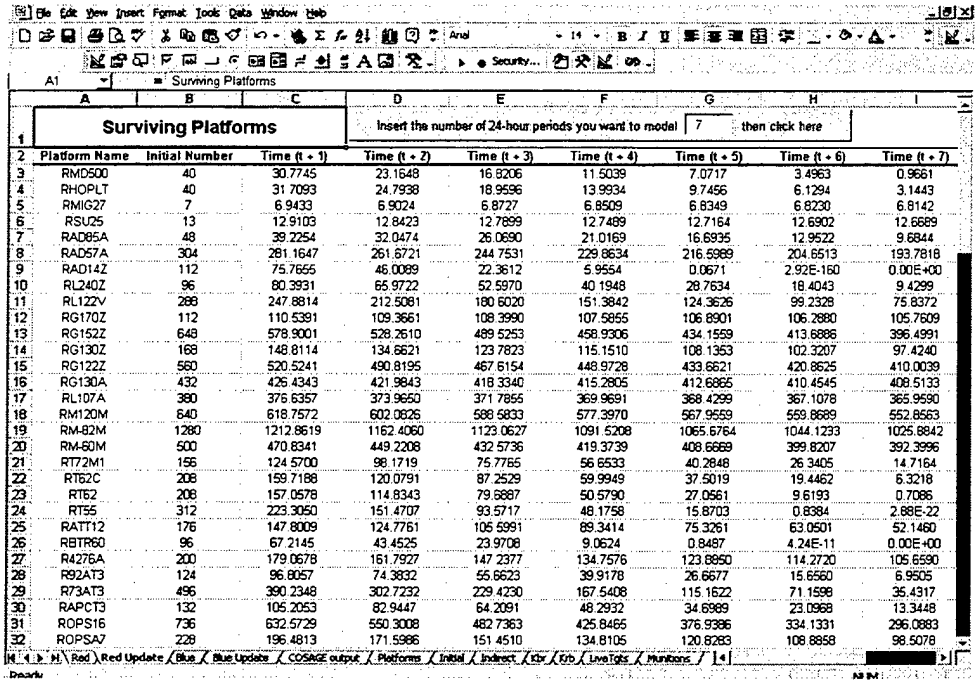
Once the number of periods is designated and the command button clicked, the model calculates surviving Red platforms and then surviving Blue platforms starting at time

$t = 0$, displaying successive 24-hour periods from left to right in the "Red Update" and "Blue Update" worksheets (see Figure 4.3).

c. Blue Update

The "Blue Update" worksheet is similar to the "Red Update" worksheet, but without the user-interface command bar. This worksheet implements the Bayesian estimates introduced in Chapter III to calculate estimates of surviving Blue platforms at 24-hour intervals, as a function of surviving Red platforms, shooting rates and kills.



Surviving Platforms

Insert the number of 24-hour periods you want to model: 7 then click here

Platform Name	Initial Number	Time (t + 1)	Time (t + 2)	Time (t + 3)	Time (t + 4)	Time (t + 5)	Time (t + 6)	Time (t + 7)

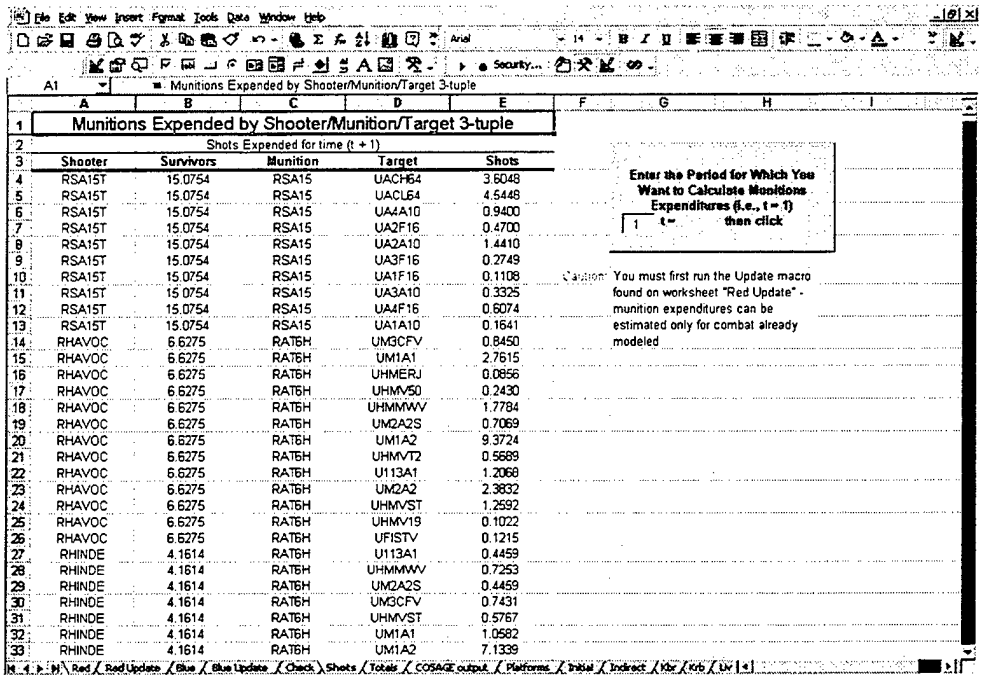
Figure 4.3 On worksheet "Red Update," when the user enters an integer value in the text box and clicks the command bar, the model automatically updates estimated surviving platforms.

d. Shots

The "Shots" worksheet utilizes 24-hour shooting rates calculated in the single-period model and surviving platforms calculated in worksheets "Red Update" and

"Blue Update" to generate estimated shots for both direct and indirect fire weapons for each shooter / munition / target 3-tuple present. These estimates do not account for target numbers equal to zero. As a result, they tend to overstate munitions expenditures; this can be corrected by introducing an indicator variable that goes to zero with target number. Re-allocation of weapons will be treated in later work. Included on the worksheet is an interface that allows the user, once the Update model is completed, to estimate munitions expenditures for a specific 24-hour period (see Figure 4.5). Once the desired 24-hour period is entered and the command button clicked, the multiple-period model populates both the "Shots" and "Totals" worksheets. The current assumption made in Chapter II, Section B, that shooting rate per Blue shooter is independent of target number, allows a somewhat naive approach to attrition calculations for successive 24-hour periods without sacrificing the plausibility of the estimates for direct and indirect fire attrition. Sample multiple-period results are included in Chapter V.



Munitions Expended by Shooter/Munition/Target 3-tuple

Shots Expended for time (t + 1)

Enter the Period for Which You Want to Calculate Munitions Expenditures (i.e., t = 1)

t = 1 then click

Caution: You must first run the Update macro found on worksheet "Red Update" - munition expenditures can be estimated only for combat already modeled

Figure 4.5 The "Shots" worksheet provides a simple interface by which the user can predict munitions expenditures for a specified 24-hour period.

e. Totals

As stated above, when the user-interface on the "Shots" worksheet is activated, the "Totals" worksheet is populated with shot data from the desired 24-hour combat period. The "Totals" worksheet then calculates total munitions expenditures, both by shooter / munition / target 3-tuple, as seen in worksheet "Shots," and as total expenditures for the user-defined 24-hour period by munition type in the "Totals" worksheet (see Figure 4.6). As expected, when compared to the single-period model, the total numbers of munitions fired by all shooters decreases in successive 24-hour periods as shooters are attrited, even though, as discussed above, shooting rate per shooter remains constant throughout the combat posture. As noted before, the calculations do not

reflect the numbers of targets present. Hence, the calculations tend to overstate the munitions expended. This will be corrected in later work.

Figure 4.6 The "Totals" worksheet provides munitions expenditures both by shooter / munition / target 3-tuple, and as totals for each munition type.

C. CHANGING COMBAT POSTURES

1. Discussion

The implementation of the multiple-period model introduces the user to the added benefit of being able to switch from one combat posture to another after each 24-hour period within the same theater. As those who have studied history know, entire wars often shift from one combat posture to another as the balance of power shifts, rarely remaining in one combat posture for more than a few days at a time. COSAGE provides the user a total of seven combat postures, which are modeled in both NEA and SWA. As implemented by many combat simulations, including CEM, battles are often represented

by a "piston" model, which is forced back and forth as the balance of power shifts from Blue to Red and vice versa (CAA, 1995). By introducing the concept of shifting combat postures, the multiple-period model may more closely predict platform survival over the entire combat duration.

2. Model Implementation

The implementation of the multiple-period model is capable of changing combat postures after each 24-hour combat period. Although the model does not include a worksheet-based interface, the procedure for switching combat postures involves minimal user input, and can be accomplished in under one minute. Additionally, because the implementation is based on COSAGE, in which all postures in a given theater share a common platform set, albeit with different initial numbers, the user need not concern himself with the possibility of data "gaps." The procedure for switching from one combat posture to another is as follows:

a. Modeling the First 24 Hours

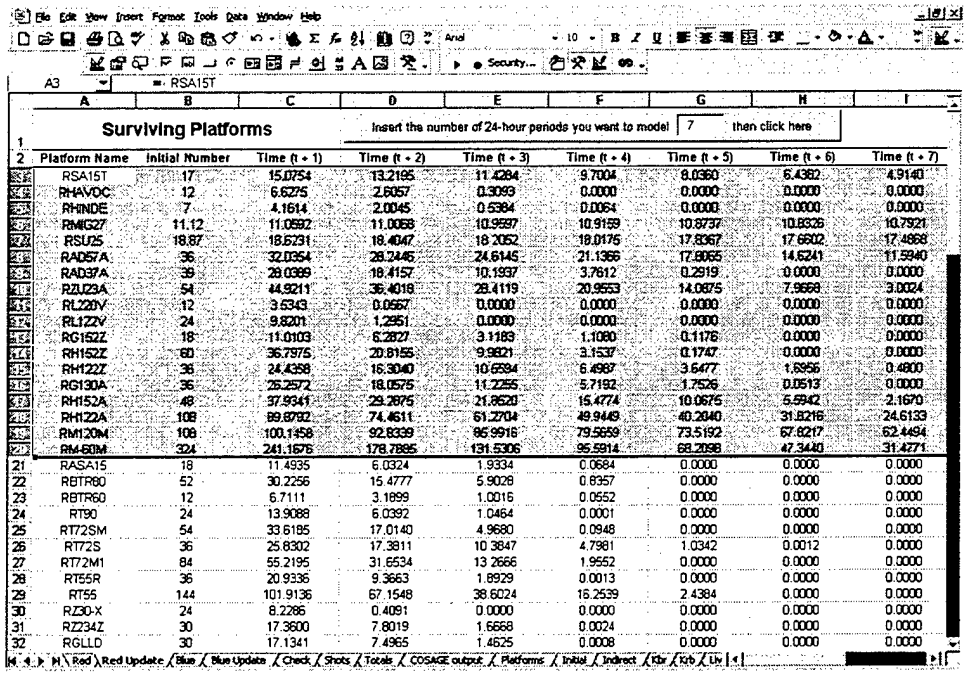
The user dictates the posture in which combat is to begin, or in which posture combat starts for a user-defined phase. Once the posture is chosen, simply run the multiple-period model for a single 24-hour period using the interface on worksheet "Red Update." At the user's discretion, the initial posture may be run for more than a single 24-hour period.

b. Formatting the Output

Once the formulation has completed the desired iterations of platform survival estimates, the output on worksheets "Red Update" and "Blue Update" requires

some quick formatting. COSAGE dictates that each posture for a given theater (NEA or SWA) begin at time $t = 0$ with the same types of platform, although many begin with different initial numbers (CAA, 1993). As a result, platform lists and the calculations associated with those lists, are interchangeable. In order to ensure that platforms simulated in the analytical model will match on a case by case basis from posture to posture, the platforms must be placed in alphabetical order. Once the desired number of 24-hour iterations is complete, the user need only alphabetize the results by selecting entire rows of data in the Excel worksheets "Red Update" and "Blue Update" (see Figure 4.7).

Once the rows containing all platform names, initial numbers and estimated survivors have been highlighted, the user need only click the Sort Ascending button on the Excel toolbar. After repeating the procedure on the "Red Update" and "Blue Update" (source) worksheets in the next dictated posture's (target) workbook, the data is ready for transfer and continued modeling. By copying the last 24-hour estimate column from the source worksheets and pasting them into the "Initial Number" column of the appropriate target worksheets, the user is ready to continue modeling combat. Because the multiple-period model implementation does not affect the worksheets "Red" and "Blue," initial platform numbers remain unchanged in these worksheets.



Surviving Platforms — Insert the number of 24-hour periods you want to model: 7 — then click here

Figure 4.7 By selecting the rows containing all platform information, the user can then alphabetize the data using the Sort Ascending icon to properly format the data.

c. Modeling Continued Combat

Now that the data from the last 24-hour combat period has been imported into the worksheets associated with the next user-dictated posture, it is ready for further use. Since shooting rates and kill probabilities are located in the "COSAGE output" worksheet of the target combat posture workbook, importing data does not in any way alter the combat characteristics of the target posture. The user may now select the number of 24-hour time steps to calculate in the new combat posture. Then, once the desired runs are complete, simply repeat the steps above to switch combat postures again.

THIS PAGE INTENTIONALLY LEFT BLANK

V. RESULTS AND CONCLUSIONS

A. RUN TYPES

As of publication, the implementation of the Discrete-Time Analytical Model (DTAM) has been run on all fourteen COSAGE summary data sets generated by Total Army Analysis 2005 (TAA05). Although many of the input parameters to COSAGE are classified, its output is not, making it an ideal candidate for further modeling exploration. DTAM should be used as a quick, unclassified tool used for estimating expected kills and munitions expenditures. However, the user must remain aware that the model is simply a tool, and that it includes some rather broad assumptions about combat modeling. While the results of the model are generally comparable to those produced during the first 48 hours of combat reported by COSAGE, there may exist outside factors unknown to the user that could make the model less accurate beyond the first 48 hours.

B. RESULTS

As shown in Appendix A, the single-period implementation of the analytical model performs well when compared to the COSAGE Killer-Victim Scoreboard, producing estimation errors in many cases well below one percent. One of the quickest and easiest ways to compare the estimates produced by the implementation of the analytical model and those produced by COSAGE is through linear regression. By regressing estimated kills on actual (observed COSAGE data) kills, the user can very quickly get a general idea of how well the implementation estimates the number of kills produced by COSAGE. To determine where potential problems lie, however, requires a different approach. While there is no best answer, one potential method to determine

goodness of fit" for each pairing of estimated versus observed COSAGE kills for the initial 48 hours of combat is formula 3.14, which is

$$error = \frac{|Estimated\ Number\ of\ Platforms\ Killed - Mean\ COSAGE\ Platforms\ Killed|}{Initial\ Number\ of\ Targets} \qquad (4.1)$$

Unlike other methods that amplify relatively small absolute errors when the observed COSAGE kills are small, this method penalizes the analytical model implementation only when the proportion of estimated targets killed differs greatly from the proportion of COSAGE observed kills for the initial 48 hours of combat. For example, for a platform with initial number 25 and observed COSAGE kills of 0.15, a kill estimate of 0.75 produces an error of 400% if $error = \frac{|Estimated\ Number\ of\ Platforms\ Killed - COSAGE\ Platforms\ Killed|}{COSAGE\ Platforms\ Killed}$. (4.2)

Expression (4.1) yields estimated kill error calculations for each platform type, displayed in Figure 5.1, which identifies potential problem cases.

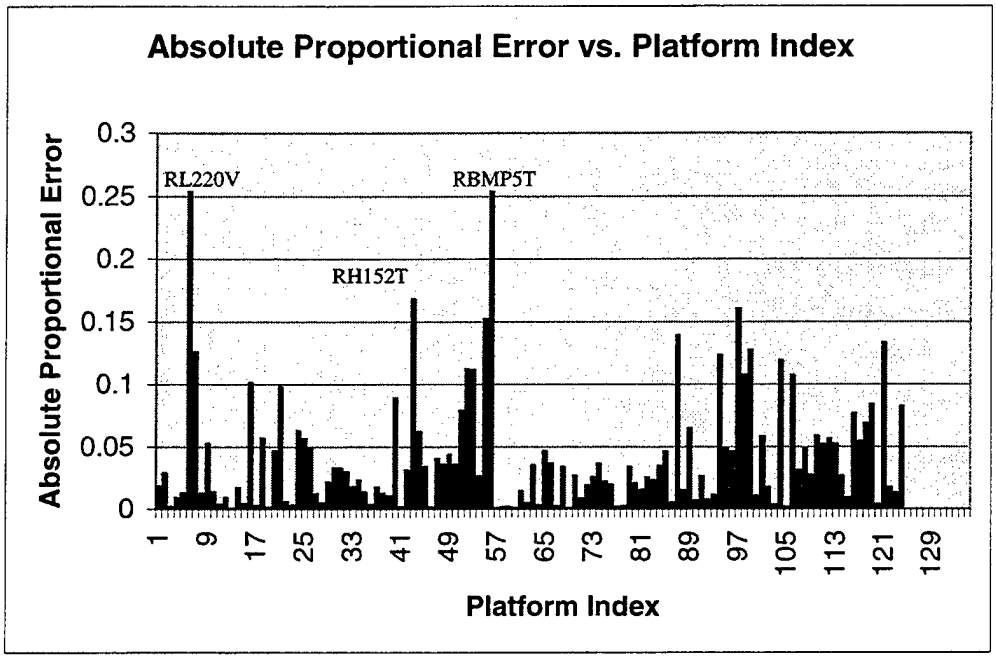

Figure 5.1 Plotting absolute proportional estimate error identifies where estimated kills produced by the analytical model implementation differ greatly from kills produced by COSAGE in the initial 48 hours of combat.

For the combat posture SWA "D" (Red Attack vs. Blue Delay), Figure 5.1 identifies three platforms for which the analytical model implementation differs significantly from COSAGE output concerning platforms killed during the initial 48 hours of combat. Table 5.1 displays these three cases in tabular form. Recall that summary data are a variable from COSAGE. Data on the number of rounds fired at each particular target are unavailable. Hence, the Bayesian estimates for survival probability include the exponent $\bar{N}_{BR}(j_B, w_B, j_R, 0) / R(j_R, 0)$ for direct fire, which assumes that each target, fired at by a weapon receives an equal allocation of all shots. In reality, each target receives only an integer number of shots, which means that some targets will receive more shots than others. For example, if a total of fifteen shots are fired at ten targets, the allocation of those fifteen shots may be explained as follows:

Let $S = 15$ (the number of shots fired)

$R = 10$ (the number of Red targets)

$\lfloor X \rfloor$ = the greatest integer in X (e.g., $\lfloor 1.7 \rfloor = 1, \lfloor 2.3 \rfloor = 2$, etc.)

Then $S = aR + b$ where b is a remainder $\left(b = S - \left\lfloor \frac{S}{R} \right\rfloor \cdot R \right)$

and $a = \left\lfloor \frac{S}{R} \right\rfloor = \left\lfloor \frac{15}{10} \right\rfloor = 1$

Hence, assuming that all targets are affected by the 15 shots, b (10) targets will receive $\left\lfloor \frac{S}{R} \right\rfloor + 1$ shots each, where 1 represents the 15 – 10 = 5 "excess" shots, while the remaining R- b (5) targets will receive only one shot each.

Platform Name	Initial Number	COSAGE Kills	Analytical Model Implementation Kills
RH152T (152mm Howitzer)	36	15.88	37.43
RBMP5T (Armored Personnel Carrier)	84	18.38	40.12
RL220V (Multiple Rocket Launching System)	48	15.12	21.92

Table 5.1 Plotting absolute proportional error identifies potential problem cases for which estimated kill proportion differs significantly from the COSAGE kill proportion for the initial 48 hours of combat. Once potential problem cases are identified, the cause should be determnined.

Examining the kill discrepancy for platform RH152T reveals the following:

Of all shooters killing RH152T in posture SWA "D," only one, UACL64 (AH-64 helicopter) fires only one munition type at RH152T, which is the Longbow missile.

Because of its accuracy, the Longbow missile produces 5.69 kills with an average of 6.12 shots at RH152T, which represents a simple kill probability of 0.93. It appears possible that the mean COSAGE data is the result of overly-optimistic kill probability input parameters, though averaged COSAGE output does not reveal the true cause. Using Equation (3.1) to determine the single shot survival probability yields a value of 0.0789. Since there are initially 36 targets, the estimated number that survive the Longbow alone is $(36)(0.0789)^{6.12/36} = 23.37$. This corresponds to 12.63 estimated kills, whereas COSAGE produces only 5.69 kills. Because the Longbow missile, fired in small numbers, produces so many expected kills, the analytical model implementation overestimates kills of platform RH152T.

1. Implementation of the Multiple-Period Model vs. COSAGE

This section examines the implementation of the multiple-period model for combat posture NEA "F" – Blue Attack vs. Red Prepared Defense. The comparison in this section involves the multiple-period model implementation, comparing its estimated kills produced by running two consecutive 24-hour periods to the results produced by a single 48-hour period modeled by COSAGE.

To examine the plausibility of the implementation of the multiple-period model for the case NEA "F," we will look at the linear regression of estimated number of kills produced by the implementation of the analytical model for two consecutive 24-hour periods versus actual kills reported by COSAGE (see Figure 5.2).

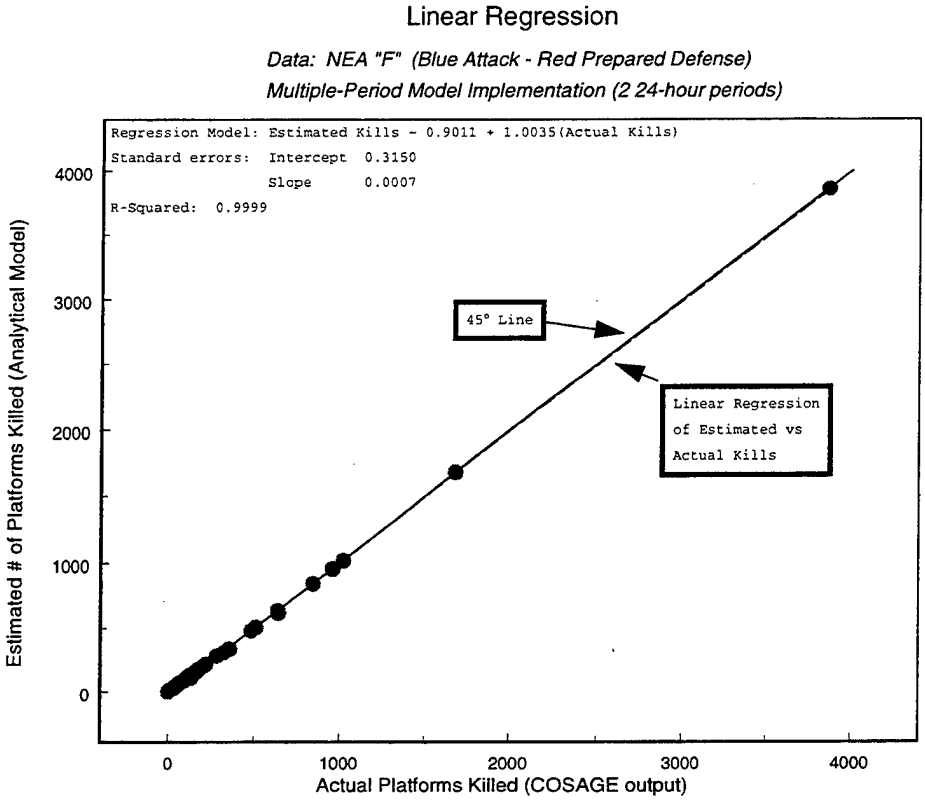

Figure 5.2 The linear regression of Estimated vs. Actual COSAGE kills confirms that the plausibility of the analytical model for estimating kills.

Based on the results shown after two consecutive 24-hour combat periods, the analytical model produces plausible results.

2. Implementation of the Multiple-Period Model vs. Implementation of the Single-Period Model

Because the single-period and multiple-period model implementations utilize the same Bayesian estimators introduced by Gaver and Jacobs, one would expect that each model implementation would produce the same estimated number of platforms killed after 48 hours of combat. In order to partially check this conjecture, we examine the linear regression of estimated multiple-period model kills versus estimated single-period model kills for the same combat posture (see Figure 5.3).

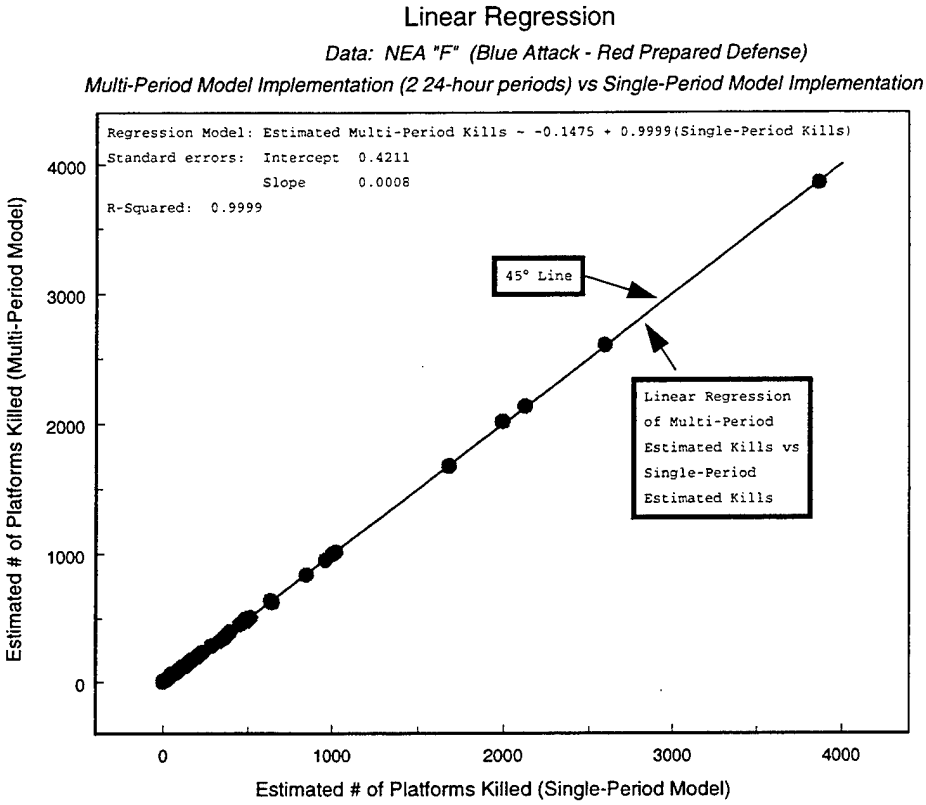

Figure 5.3 Ideally, the single-period model implementation and multiple-period model implementations should produce the same kills after 48 hours of simulated combat.

Although it appears from the plot that the single-period and multiple-period model implementations produce identical results for the estimated number of platforms killed over 48 hours of combat, the linear regression report shows otherwise. While there is measurable difference between the results from the two implementations, it is easily explained. Because the single-period model implementation models a continuous 48-hour period, it lacks the time resolution afforded by the multiple-period implementation, and as a result, calculates platform attrition only once, overlooking the attrition to shooters that will effectively diminish total estimated kills. Although its value is nearly

one, a slope value of 0.9999 may not indicate that the single-period model implementation produces the same number of platforms killed as in the multiple-period model implementation. To investigate, Figure 5.4 displays differences in the two implementations as a function of the number of targets present.

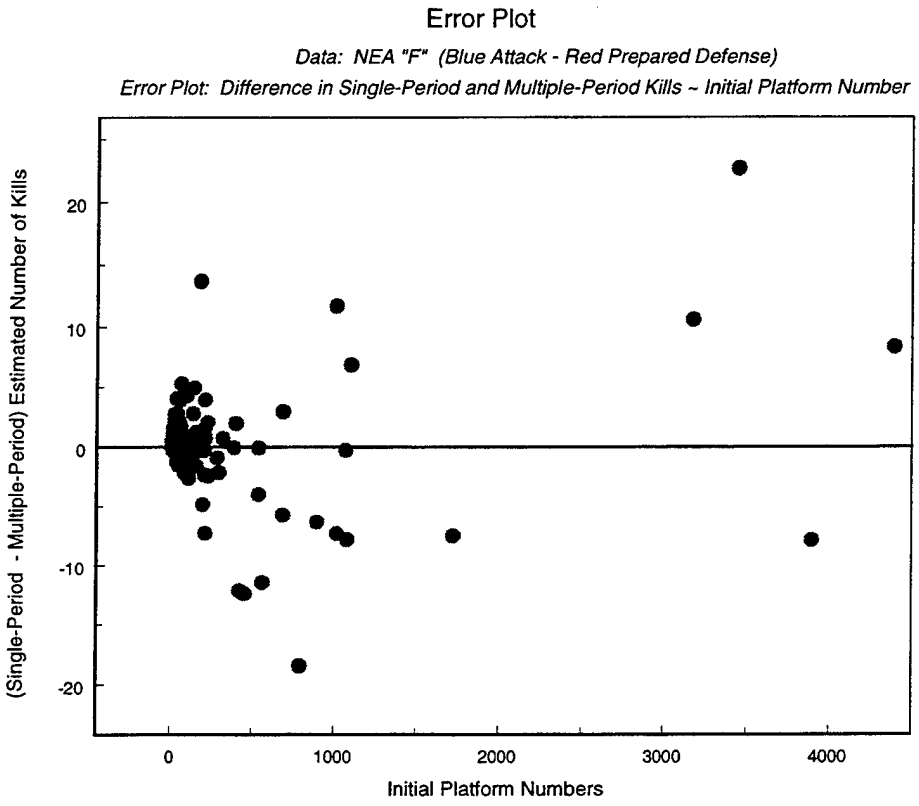

Figure 5.4 Plotting differences between the estimated kills produced by the single- and multiple-period model implementations shows that the single-period implementation does not produce a systematic bias compared to the multiple-period implementation.

3. Comparing Estimated Survivors for Different Postures

As discussed in Chapter I, COSAGE models seven different combat postures. A simple check to determine the plausibility of both the single- and multiple-period models can be accomplished by turning a *qualitative* vice a quantitative eye toward the reported

results. By recalling the different combat postures, the user should, with some sense of accuracy, be able to predict a very general outcome of the battle. For example, if the posture being modeled depicts Blue Attack vs. Red Hasty Defense (posture "N"), the user would expect to see, after several days of combat, much higher attrition rates for Red platforms than for Blue.

To provide an example of the theory outlined above, Figures 5.5 and 5.6 depict results for some platforms for seven days of combat in SWA posture "N" (Blue Attack vs. Red Hasty Defense). As expected, Blue attacking forces were able to inflict substantial attrition on Red forces fighting from a hasty defensive position. While numerous Red platforms approach zero during the first seven days of battle, the user must remember that battles rarely remain in the same combat posture for more than a few days.

Figure 5.6 After seven days of combat in posture "N" (Blue Attack vs. Red Hasty Defense), during which Blue was the attacker, Blue forces suffered only limited attrition.

In another example, Figures 5.7 and 5.8 depict numbers surviving for some platforms for seven days of combat in the SWA "H" posture (Red Attack vs. Blue Hasty Defense). From the posture description, one would expect to see far fewer estimated Red kills than in posture "N," as well as an increased number of Blue estimated kills. As expected, Red forces suffered less estimated attrition than witnessed in posture "N," and Blue forces fighting from a hasty defensive position suffered greater estimated attrition. It is useful to note that, although Red forces are offensive in posture "H," some high-priority targets are still attrited to zero over the course of seven days.

Figure 5.8 In posture "H" (Red Attack vs. Blue Hasty Defense), Blue platforms, fighting from a defensive position, suffer significantly more estimated kills than in posture "N" (Blue Attack vs. Red Hasty Defense).

In postures "N" and "H," various Red platforms are attrited to zero during seven days of combat, which may alarm the user. In the single-period implementation, the estimated number of targets killed for the first 48 hours of combat is compared to COSAGE output to ensure single-model plausibility. Once validated, the multiple-period implementation extrapolates the estimated kill rates for 24-hour periods beyond the initial 48 hours modeled in COSAGE. As a result, if the combat posture remains unchanged, estimated attrition rates calculated in the initial 48 hours are carried through successive 24-hour periods, producing seemingly high estimated kill rates.

In a final example, Figures 5.9 and 5.10 depict numbers surviving for some Red platforms for seven days of combat that starts in posture "N" (Blue Attack vs. Red Hasty Defense), then transitions to posture "F" (Blue Attack vs. Red Prepared Defense) after two days for the remainder of the seven days. As expected, attrition to some Red platforms slows when the transition is made to posture "F," producing fewer estimated kills than seven days of combat in posture "N" (Blue Attack vs. Red Hasty Defense). However, because the analytical model implementation implicitly models the combat interactions within COSAGE, fire allocation associated with posture "F" produces more estimated kills for some Red platforms than in posture "N."

Figure 5.10 After two days of combat in posture "N" (Blue Attack vs. Red Hasty Defense), the battle transitions to posture "F" (Blue Attack vs. Red Prepared Defense) for the remaining five days of battle. Note that the Red platforms surviving at time (t + 1) in posture "N" become initial numbers in posture "F."

C. BENEFITS OF THE MODEL

1. Speed

Both the single-period and multiple-period models significantly reduce the time required to obtain results for 48 hours of ground combat. Once data is received from CAA in the form of COSAGE Killer-Victim Scoreboards, the primary time requirement involved when utilizing DTAM is converting files from Unix to Windows files. After the data is properly formatted, computer processing time involves a matter of minutes vice the hours required to run COSAGE. More importantly, the analytical model "fitted to" COSAGE data from the initial 48 hours allows suggestive extrapolation to much greater times without the necessity for additional COSAGE runs.

2. Sensitivity Analysis

Because DTAM runs relatively quickly, it can be used to explore numerous "what if" questions concerning parameters, including fire allocation, firing rates and initial platform numbers. Additionally, the relative speed at which DTAM produces results allows for code modifications to add functionality or to improve existing functions without investing vast amounts of time.

D. SUGGESTED FUTURE WORK

The implementation of the model presented in this thesis is very much a work in progress. The following items are candidates for such improvement.

1. Use Additional Data From COSAGE Runs

The model implementations presented in this thesis are based on Killer-Victim Scoreboard information (e.g., average number of shots and kills) that is the average of either sixteen or twenty COSAGE runs, depending on Blue-Red force interaction

frequency. Improved estimates of platform survivability could be obtained by using COSAGE data from individual runs. This could allow a better assessment of outcome *ranges* for much longer times without the need to run COSAGE.

2. Updating Current Data

The most immediate improvement to the model is achievable through updating the data sets. The data used for this thesis was drawn from Total Army Analysis 2005 (TAA05), which was superceded by TAA07 in late 1998. TAA07 data is currently available through the Center for Army Analysis (CAA), and will remain current into the year 2001, when TAA09 will be completed. The user may wish to update the parameters using the TAA07 data, or to make any other changes that may improve the functionality of the model.

3. Introduce Mine-Clearing Capabilities

DTAM does not currently model mine-clearing operations of any kind. As stated earlier, mines are currently modeled as one platform that can not be attrited firing indirect munitions. The inclusion of such operations may greatly enhance the models' usefulness when faced with artillery-fired mines, minefields, or both.

4. Make Shot Rates Adaptive to Changing Circumstances

As mentioned, once DTAM calculates shot rates for each shooter / munition / target present in the prescribed combat posture, it uses the same shot rates per shooter / munition / target every time the given posture is revisited. Because the COSAGE Killer-Victim Scoreboard does not describe fire re-allocation, modeling fire re-allocation will require an understanding of the inner workings of COSAGE code.

5. Resolve "Excess" Kills

As noted in Chapter II, when DTAM identifies a case in which the average number of kills recorded for a particular target exceeds the average total shots fired at that target for a given munition, kills are set equal to shots fired. Future work should seek a replacement for this simplifying assumption that does not discount these "excess" kills.

6. Improve the User Interface

Although neither the single-period nor the multiple-period models require excessive user intervention, improvement is always possible. It may be possible to restructure the Visual Basic code to improve its functionality, and to make its operation virtually transparent to the user.

E. ACHIEVEMENT OF OBJECTIVE

1. Reducing Modeling Time Requirements

DTAM computes estimated numbers of platforms surviving for the 48-hour period using COSAGE data. In addition, the model analytically projects number of platforms surviving far beyond the initial 48-hour period without the need for costly postprocessor simulations. While there are obvious possible limitations to the trustworthiness of DTAM, it greatly reduces computation time requirements, which makes it ideal for multiple runs and sensitivity analysis on an exploratory, if tentative, basis.

2. Producing Expected Numbers of Platforms Surviving

As shown in the results of this chapter, DTAM is capable of quickly providing reasonable estimates for expected numbers of platforms surviving (Red and Blue). It can

also be used to project munitions needed to sustain combat. Although the implementation does not represent every munition option available in today's Army, it does represent most present-day major weapon systems and their armament, and is easily updated as new systems become available and are modeled in COSAGE.

F. SUMMARY OF RESULTS

We have developed a tool for analysts to use in modeling ground combat that will produce expected numbers of platforms surviving using COSAGE output as initial input. This model allows analysts to conduct quick "what if" investigations by altering input parameters (e.g., shooting rates, initial platform numbers, etc.) between model runs. Although the model represents additional functionality to that already available through COSAGE and other simulations, there are still numerous improvements to be made. Some of these improvements have been outlined, and others will become apparent with experience.

APPENDIX A. LINEAR REGRESSION MODELS

This appendix provides the reader one tool used to evaluate the plausibility of the single-period analytical model implementation. The linear regressions displayed compare estimated platform kills produced by the analytical model implementation during the initial 48 hours of battle to those kills produced by COSAGE. The linear regression model for combat posture NEA "D" (Blue Attack vs. Red Delay) presented in Chapter I is not displayed.
